The monocrystalline silicon in the solar panel is doped with impurities such as boron and phosphorus to create a p-n junction, which is the boundary between the positively charged (p-type) and negatively charged (n-type) regions of the silicon. This junction is what enables the solar panel to convert sunlight into electricity.

In terms of photovoltaic solar panels, monocrystalline and polycrystalline panels are the two most common options. Both incorporate silicon solar cells, the same material found in the chips of modern devices and gadgets, however it's the silicon's crystallinity that determines whether a solar cell is in fact monocrystalline or polycrystalline.
